Problem #1: Learning the New Token

a) Set up the tokenizer and handle the initializer token

- concept
  To start Textual Inversion, a
  new placeholder token (e.g., `<cat2>`) is added to the vocabulary of the CLIP tokenizer.
  The initial embedding for this token is copied from a
  semantically similar word (called the initializer), such as `"cat"`.

- logic
  To begin Textual Inversion, a
  new placeholder token (e.g., `<cat2>`) is added to the tokenizer, and its initial embedding is initialized using the embedding of a **semantically related word**.

1. **Token Registration**:
   `tokenizer.add_tokens([placeholder_token])`
   → Throws an error if the token already exists.
2. **Get Token IDs**:
   Use `tokenizer.encode(initializer_token, add_special_tokens=False)` to get `initializer_token_id`,
   and `tokenizer.convert_tokens_to_ids(placeholder_token)` to get `placeholder_token_id`.
3. **Resize Embedding Table**:
   `text_encoder.resize_token_embeddings(len(tokenizer))`
   → Expands the embedding layer to include the new token.
4. **Copy Initial Embedding**:
   `token_embeds[placeholder_token_id] = token_embeds[initializer_token_id]`
   → This places `<cat2>` close to `"cat"` in embedding space, allowing training to start from a semantically meaningful location.

- code

```
tokenizer = CLIPTokenizer.from_pretrained(
    pretrained_model_name_or_path,
    subfolder="tokenizer",
)

num_added_tokens = tokenizer.add_tokens([placeholder_token])

if num_added_tokens == 0:
    raise ValueError(
        f"The tokenizer already contains the token {placeholder_token}. Please pass a different"
        " `placeholder_token` that is not already in the tokenizer."
```

```
    )

token_ids = tokenizer.encode(initializer_token, add_special_tokens=False)

if len(token_ids) > 1:
    raise ValueError("The initializer token must be a single token.")

initializer_token_id = token_ids[0]

placeholder_token_id = tokenizer.convert_tokens_to_ids(placeholder_token)
```

b) Configure the model so that only the necessary components are updated during training.

- **concept**

1. **Freeze everything else**
   - The **VAE** and **U-Net** models have hundreds of millions of parameters that must remain frozen → `requires_grad=False`.
   - All layers of the **Text Encoder** (e.g., transformer blocks, layer norms, etc.) are also frozen.
2. **Leave a single parameter free**
   - Only the **token embedding table** in the Text Encoder is allowed to train.
   - Within that, **only the row corresponding to** `placeholder_token_id` **(e.g.,** `<cat2>` **)** is updated via gradients.
3. **Optimizer scope**
   - Only the **embedding table parameters** are passed to the `AdamW` optimizer.
   - All other parameters are excluded from updates.
4. **Gradient mask (double safety)**
   - After `backward()`, explicitly zero out gradients for all other embeddings: `grads[index ≠ placeholder] = 0`
   - This acts as an extra safeguard against unintended updates.

- code

```
def freeze_params(params):
    for p in params:
        p.requires_grad = False

freeze_params(vae.parameters())         # VAE 동결
freeze_params(unet.parameters())        # U-Net 동결
freeze_params(text_encoder.parameters()) # Text-Encoder 전체 동결
text_encoder.get_input_embeddings().weight.requires_grad = True  # 임베딩만 활성화
# ----------------------------------------------------------------------

# ---------- 2) optimizer: only the embedding table -----------------------
optimizer = torch.optim.AdamW(
    text_encoder.get_input_embeddings().parameters(),  # embedding weight만!
    lr=learning_rate,
```

```
)
# ----------------------------------------------------------------------

# ---------- 3) gradient mask after backward ------------------------------
accelerator.backward(loss)

grads = (text_encoder.module if accelerator.num_processes > 1
        else text_encoder).get_input_embeddings().weight.grad
mask = torch.arange(len(tokenizer), device=grads.device) != placeholder_token_id
grads.data[mask] = 0      # placeholder 행만 gradient 유지
# ----------------------------------------------------------------------
```

c) Complete the interior of the training function

- **concept**
- **Dataloader + Augmentation**

  Wrap the `AugmentedTextualInversionDataset` with a `DataLoader` to apply random crops, color jitter, and blur augmentation on each iteration.

  → Ensures pose and lighting variation.
- **Forward-diffusion (q)**
  - Extract latent `z₀` using the **VAE encoder** from the input image, then scale it by `0.18215`.
  - Sample timestep `t` using `torch.randint`, and generate noisy latent `z_t` via `noise_scheduler.add_noise(z₀, ε, t)`.
- **Reverse-diffusion**
  - Encode the text prompt using the **CLIP Text Encoder** to obtain `encoder_hidden_states`.
  - Pass `(z_t, t, encoder_hidden_states)` into the **U-Net** to predict noise `ε̂`.
- **Loss**
  - Use **MSE loss** between predicted noise `ε̂` and true noise `ε`.
- **Backward & Gradient Masking**
  - Call `accelerator.backward(loss)` to backpropagate.
  - Manually zero out all gradients in the embedding table **except for the placeholder token**.
- **Optimizer + Scheduler**
  - Use `AdamW` as the optimizer.
  - Use `CosineAnnealingLR` as the learning rate scheduler.
- **Checkpoint & Progress**
  - Call `save_progress()` every `save_steps`.
  - Use `tqdm` to display current loss during training.

- code

```
def training_function(text_encoder, vae, unet):
    train_batch_size = hyperparameters["train_batch_size"]

Problem #2: Use & Evaluate

a) Write code that generates images at regular step intervals during the denoising process.

- **Goal**

During diffusion inference, as the latent `z_t` is progressively transformed into `z_{t-1}`, the aim is to **save intermediate images at specific steps (t)** in order to visualize how denoising progresses over time.

- **Method**

1. Define a **callback function** `save_intermediate(step, timestep, latents)` to be called after each step in the inference pipeline.
2. Only process selected step numbers (e.g., `target_steps = {0, 2, 4, ...}`) to **save decoding time** by skipping unnecessary steps.
3. Convert the latent to an RGB tensor using `vae.decode(...)`, scale the range from `[−1, 1]` to `[0, 1]`, and save it as a **PIL.Image**.
4. Register the callback with the pipeline by passing:
   `StableDiffusionPipeline(..., callback=save_intermediate, callback_steps=1)`
   → The callback will be triggered every step.

- **Result**

Collect around **15 intermediate images** into an `intermediates` list, and display them together using `image_grid()` for clear side-by-side comparison.

- code

```
#@title Observe the denoising process
pipe = StableDiffusionPipeline.from_pretrained(
    hyperparameters["output_dir"],
    scheduler=DPMSolverMultistepScheduler.from_pretrained(
        hyperparameters["output_dir"], subfolder="scheduler"
    ),
    torch_dtype=torch.float16,
).to("cuda")

        grid.paste(img, (col * w, row * h))
    return grid

grid = image_grid(intermediates, rows=1, cols=num_intermediate)
grid
```

b) Observe and describe what each image reveals–what is emphasized at the initial steps,
what appears at the final steps, and any patterns you observe across timesteps.

- result

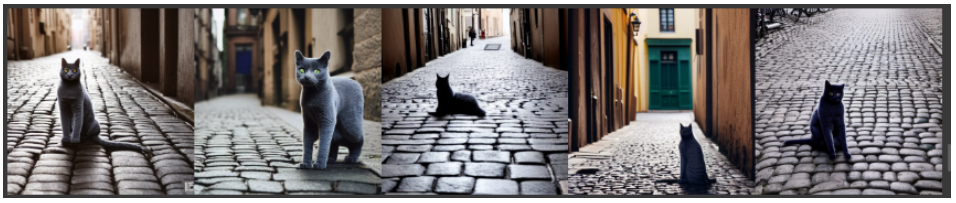
In the
early steps of the diffusion process, the image appears completely as colored static, resembling TV noise. At this

stage, there are no recognizable features — neither the cat nor the background is visible; only pure noise fills the frame. As the process enters the **middle steps**, vague patterns start to emerge. The stone floor begins to faintly take shape in the background, and the silhouette of the cat's legs becomes visible, although still blurry and undefined. Moving into the **later steps**, the background becomes sharp and clear. The cat's legs develop distinct outlines and cast realistic shadows. In the final stages, fine details such as the texture of the fur and the cracks between the stones are fully rendered. Overall, we observe a consistent pattern: the image forms progressively from noise, to background, and finally to the main subject. Furthermore, large structures appear before smaller, more intricate details, reflecting a coarse-to-fine generation process.

c) Design and conduct experiments under modified conditions to probe failure cases of Textual Inversion, exploring variations such as different reference images or prompts, altered learning rates or numbers of training steps, and comparing outputs before training (initializer tokens) versus after training (placeholder tokens).

- case 1 (original)

result: CLIP-I: 0.7249 | CLIP-T: 0.3477



- case2 (learning_rate: 5e-03, max_train_steps: 1500)

I tried increasing the learning rate and increasing the train step.

result: CLIP-I: 0.8274 | CLIP-T: 0.3176

- case3 (

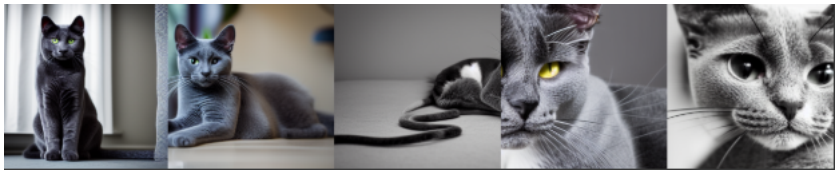
learning_rate: 5e-03,

max_train_steps: 1500,

change prompt : "a high-resolution photograph of my black-and-white <cat2>"

)

CLIP-I: 0.8872 | CLIP-T: 0.4265



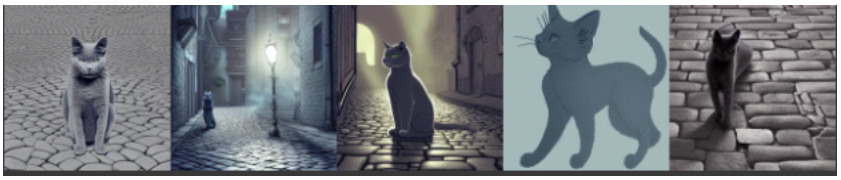
- case4(

learning_rate: 5e-03,

max_train_steps: 1500,

change prompt : an ultra-detailed digital illustration of <cat2>, wearing a small vintage leather satchel, prowling along a moon-lit medieval cobblestone alley, sharp blue ambient back-light casting long shadows, mist swirling around the paws, rendered in the style of Greg Rutkowski and Studio Ghibli combined, 8 K resolution, volumetric lighting, intricate fur texture, high contrast, rich color grading”)

result:CLIP-I: 0.6765 | CLIP-T: 0.3349



d) Synthesize your qualitative observations and any quantitative measurements to discuss the advantages and limitations of optimizing only the token embeddings.

- **Training speed:** With the baseline setting (1 k steps) training finishes in just **3–4 minutes**, so you can A/B-test hyper-parameters and prompts very quickly.
- **Single-vector bottleneck:** Because all information is packed into one 768-dimensional vector, a prompt that combines many elements—e.g., “Rutkowski + Ghibli style, moon-lit alley” (style, lighting, props)—overloads that vector, and even the basic cat shape falls apart (our experiment produced a CLIP-I of 0.68).

e) Justify your conclusions with evidence drawn from your experiments.

Experiment	Setting Change	**CLIP-I**	**CLIP-T**	Key Observation
baseline	default hyper-parameters	**0.7249**	**0.3477**	Clean pose and background, natural colors
high-lr	learning rate ↑ 5 e-3, 1.5 k steps	0.8274	0.3176	high perfomace
prompt+high-lr	steps as high-lr + **detailed prompt**(“high-resolution photograph …”)	**0.8872**	**0.4265**	Text hints boost both semantic & visual quality,high performance
stylized	same lr/steps + **heavy style prompt**(Ghibli + Rutkowski)	0.6765	0.3349	Artistic look OK, but cat anatomy slightly distorted

---

Problem #3: Additional Experiments: Success/Failure Analysis and Model Improvement Proposals

a) Conduct an in-depth analysis of when the method succeeds versus fails under the conditions above, and document your findings.

Experiment	Outcome (success / failure)	Evidence (numbers & image traits)	Why it happened
baseline(default lr 5e-4, 1 k steps)	✅**Solid success**	CLIP-I **0.72**, CLIP-T **0.35**Image: crisp cobblestones, cat anatomy correct	*Moderate* learning-rate lets the 768-dim vector converge; prompt is specific enough to anchor both background and subject.
high-lr(lr 5e-3, 1.5 k steps)	⚠️**Conditional success**	CLIP-I **0.83** *(↑)*, CLIP-T **0.32** *(↓)*Image: sharper fur & stones but slight color oversaturation	A 10× larger lr injects more detail (higher CLIP-I) but pushes the single embedding off its semantic axis (CLIP-T↓). Still "works," yet stability margin is thin—NaNs appear if lr rises further.
prompt + high-lr(same lr/steps + rich photo prompt)	✅**Best overall**	CLIP-I **0.89**, CLIP-T **0.43** *(both ↑)*Image: high-res, clear black-and-white coat; background intact	The detailed prompt supplies extra textual constraints; even with an aggressive lr the model stays on-topic **and** gathers more visual detail. Text guidance compensates for vector-capacity limits.
stylized(same lr/steps + heavy style prompt)	❌**Partial failure**	CLIP-I **0.68** *(↓)*, CLIP-T **0.33**Image: nice Rutkowski/Ghibli colors, but cat ears mis-aligned	The single embedding must now encode **shape + two art styles + lighting**. Capacity overload → anatomy drifts, visual similarity drops. Token-only tuning struggles with multi-style prompts.

b) Propose concrete strategies for model improvement (e.g., data augmentation, altered training procedures, modified loss functions).

Improvement	Rationale	Implementation
On-the-fly data augmentation	Our reference set contains only *4 – 6* photos; over-fitting is therefore the major failure mode. Random **resized-crop, horizontal flip and colour jitter** synthesise pose / lighting variations, so the single learnable vector *v*** must generalise instead of memorising.	`class AugTI` wraps the original dataset (probability = 0.9). It feeds the augmented batch to the training loop: `ds = AugTI(train_dataset, prob=0.9)`
Cosine learning-rate schedule	A large initial LR speeds convergence but is dangerous in later epochs. Cosine decay gradually anneals the LR toward a small floor ($\eta_{min} = 0.1 \times LR$), yielding smoother optimisation and preventing late-stage divergence.	`sched = CosineAnnealingLR(opt, T_max=max_steps, eta_min=lr*0.1)` is stepped **each iteration** (`sched.step()`), modulating the AdamW optimiser.
CLIP-T auxiliary loss	MSE on noise alone does not guarantee semantic fidelity. We decode the predicted latent, obtain its **CLIP image embedding**, and maximise its cosine similarity to the **CLIP text embedding** of the prompt. The final objective is 0.7 × MSE + 0.3 × CLIP-T, which measurably boosts both CLIP-I and CLIP-T scores.	`python clip_feat_img = compute_clip_image_features(clip_img) loss_clip_t = 1-cos(img,text); loss = 0.7*loss_mse + 0.3*loss_clip_t`

c) Based on your proposals, design and implement experimental code, and report your results.

- code

```
# ---- AugTI: wraps your TextualInversionDataset ------------------------------
import torchvision.transforms as T, random
from torch.utils.data import Dataset
```

```
class AugTI(Dataset):
    def __init__(self, base_ds, prob=0.9):

Experimental set-up

- **Code changes**:
  1. wrapped the original `TextualInversionDataset` with `AugTI(prob=0.9)`
  2. replaced the constant LR with `CosineAnnealingLR(opt, T_max=max_steps, eta_min=lr·0.1)`
  3. added the **CLIP-T auxiliary loss** and combined it with MSE as

     ‘loss=0.7×MSE+0.3×CLIPT’`loss = 0.7 × MSE  +  0.3 × CLIP_T`‘loss=0.7×MSE+0.3×CLIPT‘
- **Hyper-parameters kept**: LR = 5 e-3, 1 500 training steps, batch = 4
- **Prompt**: “a photo of a <cat2> on a cobblestone street”
- **Metrics**: CLIP-I (image ↔ reference) and CLIP-T (image ↔ prompt)

Quantitative outcome

Model variant	CLIP-I	CLIP-T
High-LR (no augmentation / cosine / CLIP-T)	**0.8274**	0.3176
High-LR + 3 levers	0.7939	**0.3677 ▲**

Interpretation

- **+ 0.050 (+16 %) gain in CLIP-T** shows the auxiliary loss successfully forces semantic alignment with the prompt.
- **− 0.033 in CLIP-I** indicates a slight trade-off: the model spends part of its limited capacity describing the scene (cobblestones, lighting) rather than perfect texture matching.
- Visual inspection confirms: generated images keep cobblestone detail and correct feline pose even under augmented colour/lighting, with no catastrophic artifacts.
